

# More Efficient Sorting: Mergesort and Quicksort

# Recursive Sorts

Recursive sorts Divide the data roughly in half and are called Again on the smaller data sets. This is called the Divide-and-Conquer paradigm. We will see 2 recursive sorts:

- Merge Sort
- QuickSort

# Divide-and-Conquer

- ◆ **Divide-and-conquer** paradigm:
  - **Divide**: divide one large problem into 2 smaller problems of the same type.
  - **Recur**: solve the 2 subproblems.
  - **Conquer**: combine the 2 solutions into a solution to the larger problem.
- ◆ The base case for the recursion are subproblems of manageable size, usually 0 or 1.

**Merge-sort** is a sorting algorithm based on the divide-and-conquer paradigm

# Merge Sort

# Merge-Sort

Merge-sort on an input sequence  $S$  with  $n$  elements consists of three steps:

- **Divide**: partition into 2 groups of about  $n/2$  each
- **Recur**: recursively sort  $S_1$  and  $S_2$
- **Conquer**: merge  $S_1$  and  $S_2$  into a unique sorted sequence

# Merging Two Sorted Sequences

- ◆ The conquer step merges the 2 sorted sequences  $A$  and  $B$  into one sorted sequence  $S$
- ◆ *How: Compare the lowest element of each of  $A$  and  $B$  and insert whichever is smaller.*
- ◆ Merging two sorted sequences, each with  $n/2$  elements and implemented by means of a doubly linked list, takes  $O(n)$  time

2 5 6 9 12 15 20 27 A

4 7 10 13 16 B

S 2 4 5 6

# Merging Two Sorted Sequences

**Algorithm** *merge*(*A*, *B*)

**Input** sorted sequences *A* and *B*

**Output** sorted sequence of  $A \cup B$

*S*  $\leftarrow$  empty sequence

**while** *A.isEmpty()*  $\wedge$  *B.isEmpty()*

**if** *isLessThan*(*A.first().element()*, *B.first().element()*)

*S.insertLast*(*A.remove(A.first())*)

**else**

*S.insertLast*(*B.remove(B.first())*)

**while** *A.isEmpty()*

*S.insertLast*(*A.remove(A.first())*)

**while** *B.isEmpty()*

*S.insertLast*(*B.remove(B.first())*)

**return** *S*

*Not In-Place*

# Merge-Sort

**Algorithm** *mergeSort(S)*

**Input** sequence  $S$  with  $n$  elements,

**Output** sequence  $S$  sorted

**if**  $S.size() > 1$

$(S_1, S_2) \leftarrow \text{partition}(S, n/2)$

*mergeSort*( $S_1$ )

*mergeSort*( $S_2$ )

$S \leftarrow \text{merge}(S_1, S_2)$

Not In-Place

# Merge-Sort Tree

An execution of merge-sort is depicted by a binary tree

- each node represents a recursive call of merge-sort and stores
  - ◆ unsorted sequence before the execution and its partition
  - ◆ sorted sequence at the end of the execution
- the root is the initial call
- the children are calls on subsequences
- the leaves are calls on sequences of size 0 or 1

# Execution Example

## ◆ Partition

# Analysis of Merge-Sort

- ◆ The height  $h$  of the merge-sort tree is  $O(\log n)$ 
  - at each recursive call we divide in half the sequence,
- ◆ The overall amount of work done at the nodes of depth  $i$  is  $O(n)$ 
  - we partition and merge  $2^i$  sequences of size  $n/2^i$
  - we make  $2^{i+1}$  recursive calls
- ◆ Thus, the total running time of merge-sort is  $O(n \log n)$

depth	#seqs	size
-------	-------	------

0	1	$n$
---	---	-----

1	2	$n/2$
---	---	-------

$i$	$2^i$	$n/2^i$
-----	-------	---------

-----	-----	-----

# Quick-Sort

# Quick-Sort

◆ **Quick-sort** is a sorting algorithm based on the divide-and-conquer paradigm:

- **Divide**: pick an element  $x$  (called **pivot**) and partition  $S$  into
  - ◆  $L$  elements less than  $x$
  - ◆  $E$  elements equal  $x$
  - ◆  $G$  elements greater than  $x$
- **Recur**: sort  $L$  and  $G$
- **Conquer**: join  $L$ ,  $E$  and  $G$

Not In-Place

### *QuickSort( $S$ )*

$i \leftarrow \text{PIVOT}$

$x \leftarrow S.\text{elemAtRank}(i)$

$(L, E, G) \leftarrow \text{Partition}(S, x)$

*QuickSort*( $L$ )

*QuickSort*( $G$ )

combine  $L, E, G$

In this example the PIVOT is chosen randomly, but we could decide always to choose the first element of the array, or the last.

# Partition

Not in-place

- ◆ We partition an input sequence as follows:
  - We remove, in turn, each element  $y$  from  $S$  and
  - We insert  $y$  into  $L$ ,  $E$  or  $G$ , depending on the result of the comparison with the pivot  $x$
- ◆ Each insertion and removal is at the beginning or at the end of a sequence, and hence takes  $O(1)$  time
- ◆ Thus, the partition step of quick-sort takes  $O(n)$  time

**Algorithm** *partition*( $S, p$ )

**Input** sequence  $S$ , position  $p$  of pivot

**Output** subsequences  $L$ ,  $E$ ,  $G$  of the elements of  $S$  less than, equal to, or greater than the pivot, resp.

$L, E, G \leftarrow$  empty sequences

$x \leftarrow S.remove(p)$

**while**  $!S.isEmpty()$

$y \leftarrow S.remove(S.first())$

**if**  $y < x$

$L.insertLast(y)$

**else if**  $y = x$

$E.insertLast(y)$

**else**  $\{y > x\}$

$G.insertLast(y)$

**return**  $L, E, G$

# Quick-Sort Tree

- ◆ An execution of quick-sort is depicted by a binary tree
  - Each node represents a recursive call of quick-sort and stores
    - ◆ Unsorted sequence before the execution and its pivot
    - ◆ Sorted sequence at the end of the execution
  - The root is the initial call
  - The leaves are calls on subsequences of size 0 or 1

# Execution Example

## ◆ Pivot selection

# Execution Example (cont.)

◆ Partition, recursive call, pivot selection

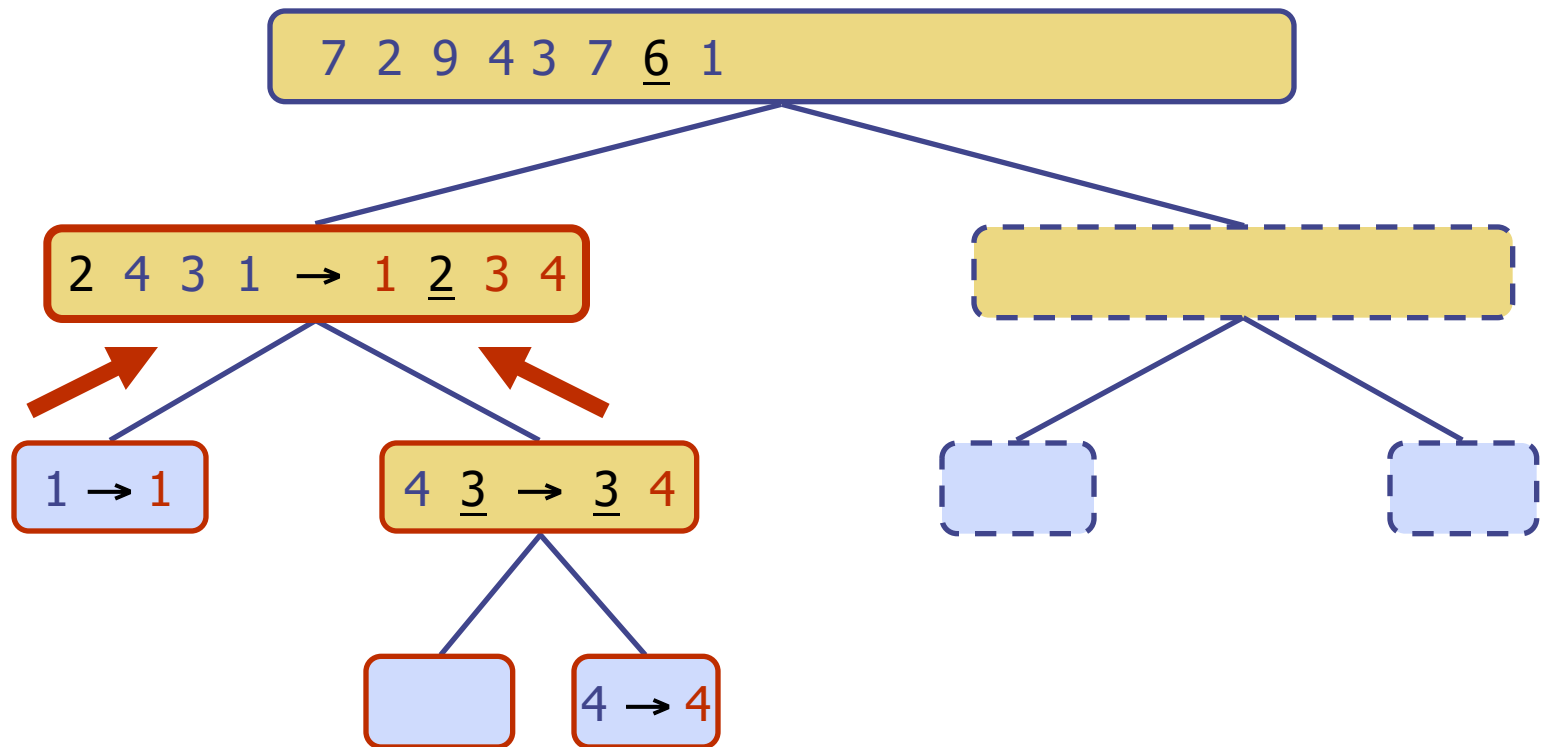

# Execution Example (cont.)

◆ Partition, recursive call, base case

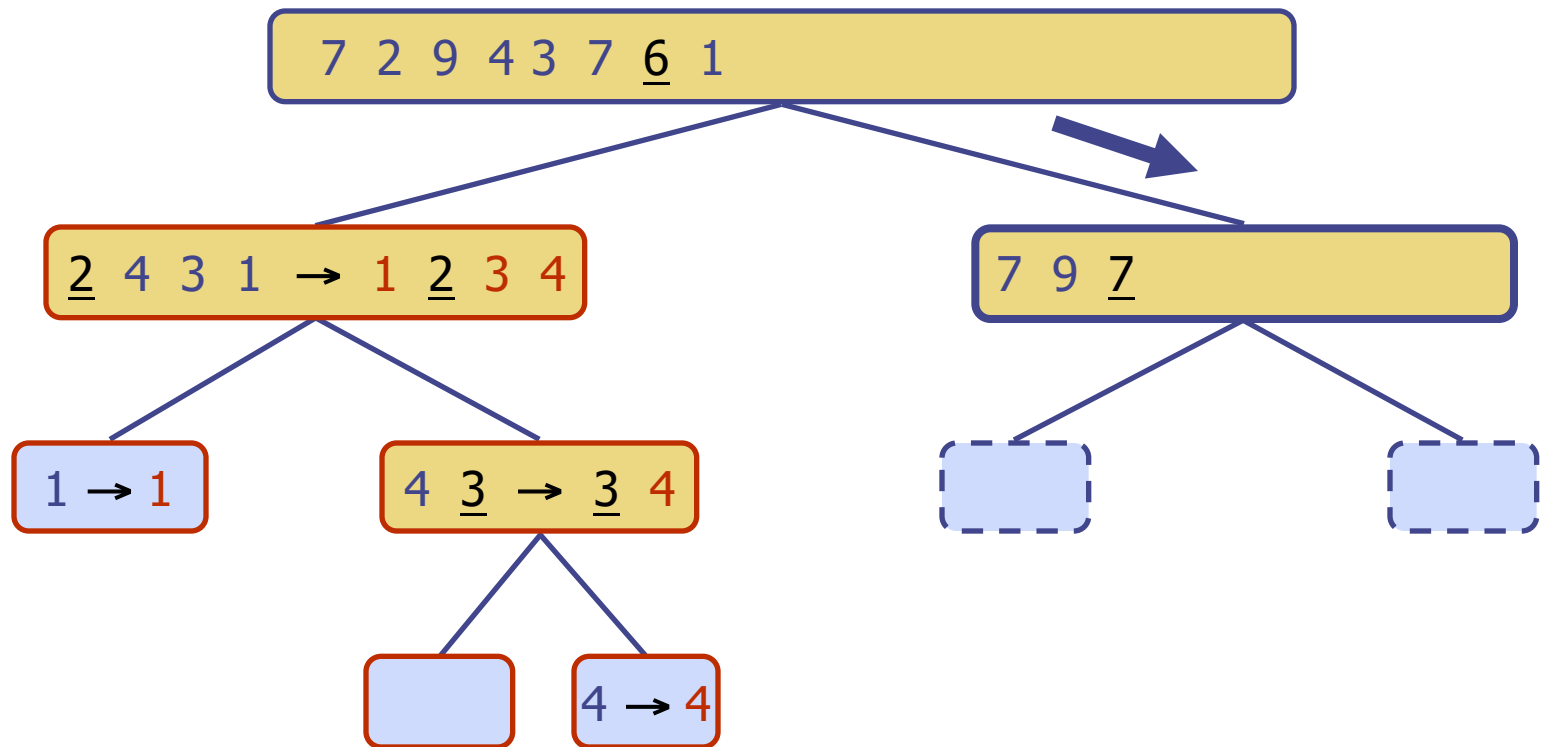

# Execution Example (cont.)

◆ Recursive call, ..., base case, join

# Execution Example (cont.)

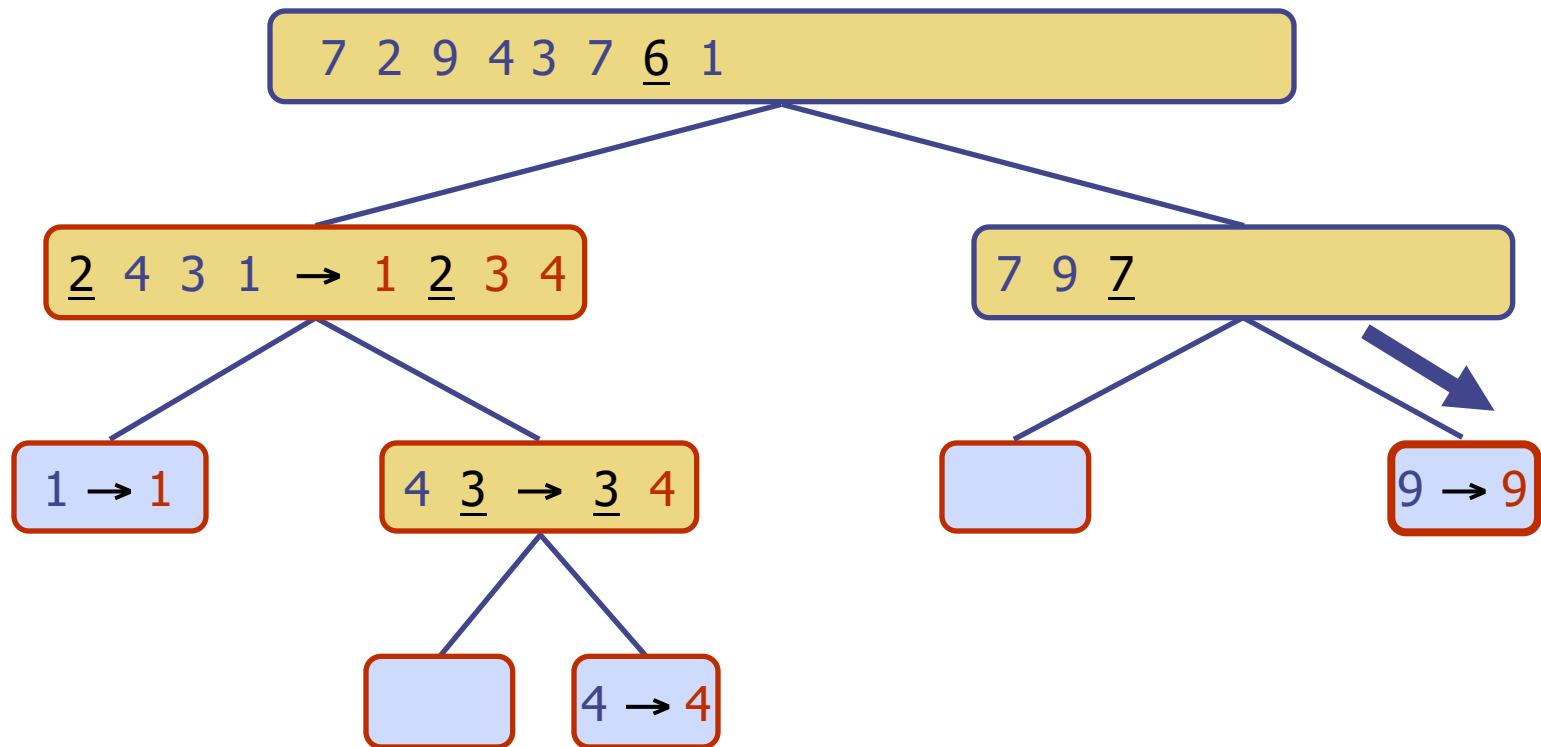

◆ Recursive call, pivot selection

# Execution Example (cont.)

◆ Partition, ..., recursive call, base case

# Execution Example (cont.)

◆ Join, join

# In-Place Quick-Sort

In the partition step, we use replace operations to rearrange the elements of the input sequence such that

- the elements less than the pivot have rank less than  $h$
- the elements equal to the pivot have rank between  $h$  and  $k$
- the elements greater than the pivot have rank greater than  $k$

◆ The recursive calls consider

- elements with rank less than  $h$
- elements with rank greater than  $k$

# In-Place Quick-Sort

Divide step:  $l$  scans the sequence from the left, and  $r$  from the right.

A swap is performed when  $l$  is at an element larger than the pivot and  $r$  is at one smaller than the pivot.

# In Place Quick Sort (contd.)

A final swap with the pivot completes the divide step

# In-Place Quick-Sort

**Algorithm** *inPlaceQuickSort*( $S, l, r$ )

**Input** sequence  $S$ , ranks  $l$  and  $r$

**Output** sequence  $S$  with the elements of rank between  $l$  and  $r$   
rearranged in increasing order

**if**  $l \geq r$

**return**

$i \leftarrow$  a random integer between  $l$  and  $r$

$x \leftarrow S.\text{elemAtRank}(i)$

$(h, k) \leftarrow \text{inPlacePartition}(x)$

*inPlaceQuickSort*( $S, l, h - 1$ )

*inPlaceQuickSort*( $S, k + 1, r$ )

# In Place Partition

- ◆ Repeat until  $l$  and  $r$  cross:
  - $l$  traverse the array from left to right until it finds an element  $\geq$  pivot
  - $r$  traverse the array from right to left until it finds an element  $<$  pivot
  - Swap elements at indices  $l$  and  $r$

**Algorithm** *inPlacePartition*( $p, s, e$ )

**Input:** position  $p$  of the pivot;  $s$  and  $e$  are the sequence limits

**Output:**  $l$  and  $r$  such that:

$r-1$  = index of the last element smaller than the pivot

$l+1$  = index of the first element larger than the pivot

$l \leftarrow s, r \leftarrow e-1$

swap  $S[p]$  with  $S[e], p \leftarrow e$

while  $l \leq r$

    while  $S[l] < S[p]$  and  $r \geq l$

$l \leftarrow l+1$

    while  $S[r] \geq S[p]$  and  $r \geq l$

$r \leftarrow r-1$

    if  $r > l$  swap  $S[r]$  with  $S[l]$

swap  $S[l]$  with  $S[p]$

return  $r+1, l$

# In Place Quick-sort

```
1  /** Sort the subarray S[a..b] inclusive. */
2  private static <K> void quickSortInPlace(K[ ] S, Comparator<K> comp,
3                                          int a, int b) {
4      if (a >= b) return;          // subarray is trivially sorted
5      int left = a;
6      int right = b-1;
7      K pivot = S[b];
8      K temp;                      // temp object used for swapping
9      while (left <= right) {
10         // scan until reaching value equal or larger than pivot (or right marker)
11         while (left <= right && comp.compare(S[left], pivot) < 0) left++;
12         // scan until reaching value equal or smaller than pivot (or left marker)
13         while (left <= right && comp.compare(S[right], pivot) > 0) right--;
14         if (left <= right) {      // indices did not strictly cross
15             // so swap values and shrink range
16             temp = S[left]; S[left] = S[right]; S[right] = temp;
17             left++; right--;
18         }
19     }
20     // put pivot into its final place (currently marked by left index)
21     temp = S[left]; S[left] = S[b]; S[b] = temp;
22     // make recursive calls
23     quickSortInPlace(S, comp, a, left - 1);
24     quickSortInPlace(S, comp, left + 1, b);
25 }
```

# Worst-case Running Time

- ◆ The worst case for quick-sort occurs when the pivot is the unique minimum or maximum element
- ◆ One of  $L$  and  $G$  has size  $n - 1$  and the other has size 0
- ◆ The running time is proportional to the sum
$$n + (n - 1) + \dots + 2 + 1$$
- ◆ Thus, the worst-case running time of quick-sort is  $O(n^2)$

depth time

# Expected Running Time

Consider a recursive call of quick-sort on a sequence of size  $s$

- **Good call:** the sizes of  $L$  and  $G$  are each less than  $3s/4$
- **Bad call:** one of  $L$  and  $G$  has size greater than  $3s/4$

◆ A call is good with probability  $1/2$   
(for an element, the expected number of calls until a good call is 2)

◆ Hence, for a node of depth  $i$ , we expect that

- $i/2$  ancestor nodes are associated with good calls
- the expected size of the input sequence for the current call is at most  $(3/4)^{i/2}n$

# Expected Running Time

- ◆ Thus, we have
  - For a node of depth  $2\log_{4/3} n$ , the expected size of the input sequence is one  $((3/4)^{((2\log_{4/3} n)/2)} n = 1)$
  - The expected height of the quick-sort tree is  $O(\log n)$
- ◆ The overall amount of work done at the nodes of the same depth of the quick-sort tree is  $O(n)$
- ◆ Thus, the expected running time of quick-sort is  $O(n \log n)$
